

AMENDMENTS TO THE CLAIMS:

1. (Currently Amended) A homogenization valve comprising having:

an outer case;

a homogenization mechanism contained in the outer case and having at least two ~~[[one]]~~ homogenization devices ~~device~~; said at least two ~~[[one]]~~ homogenization devices ~~device~~ defining a high pressure chamber in communication with a channel for feeding a fluid under high pressure to be homogenized, a low pressure chamber in communication with a channel for discharging the homogenized fluid under low pressure; said high pressure chamber being in communication with said low pressure chamber through a ~~port for the blow-by~~ port of said fluid;

means for actuating movable assemblies that control a height of a working gap of the blow-by port of said fluid; and

wherein said ~~valve wherein~~ comprises at least two distinct homogenization devices are connected with a same feeding channel and with a same discharge channel, and

wherein said at least two homogenization devices define correspondent distinct and coplanar annular gaps, serving as ports for the blow-by of the fluid.

2. (Currently Amended) A valve as claimed in claim 1, wherein said at least two homogenization devices have a cylindrical shape and are circumferentially positioned about a central axis, distanced from each other by $360^\circ/n$, where n is the number of homogenization devices.

3. (Currently Amended) A valve as claimed in claim 1, wherein each of said at least two homogenization devices ~~device~~ has:

a movable assembly housed in a cavity of the outer case and having a lower piston defining with the inner surface of a compartment the high pressure chamber and an upper piston defining the low pressure chamber with the inner surface of an additional compartment; said chambers having the shape of cylinders with annular cross section;

a ring or impact head, radially projecting from the lateral surface of said movable assembly and at least partially superposed to a projection of a passage head, defines a blow-by port together with said projection.

4. (Currently Amended) A valve as claimed in claim 3, wherein said movable assembly is capable of axially sliding in both direction within said cavity, constituted by various elements with a cylindrical cavity superposed according to a longitudinal axis, by said actuating means, to control the amplitude of the blow-by port.

5. (Original) A valve as claimed in claim 4, wherein said actuating means has a hydraulic or pneumatic cylinder, connected to a plate that is operatively active on the movable assembly of all the devices.

6. (Currently Amended) A valve as claimed in claim 1, wherein the at least two homogenization devices are connected to the feeding channel by means of radial union fittings facing said feeding channel in positions that are circumferentially distanced from each other by $360^\circ/n_1$ where n is the number of homogenization devices.

7. (Currently Amended) A valve as claimed in claim 1, wherein the at least two homogenization devices are connected to the discharge channel by means of axial union fitting facing said discharge channel in positions that are circumferentially distanced from each other by $360^\circ/n$, where n is the number of the homogenization devices.

8. (Original) A valve as claimed in claim 1, wherein said feeding channel is centrally positioned.

9. (Currently Amended) A valve as claimed in claim 1, ~~having a~~ wherein each of said movable assemblies comprises ~~assembly constituted by~~ an upper piston and a lower piston, which, in turn, ~~constituted by~~ comprise a set of elements.

10. (Original) A valve as claimed in claim 9 wherein the set of elements in the case of the lower piston comprises: an appropriately contoured cylindrical body provided with a compartment for housing a bushing or bearing made of frictionless material and locked in turn by an element mated with the cylindrical body and the bushing and fastened to the cylindrical body by means of a connecting element; and in the case of the upper piston it comprises an appropriately contoured cylindrical body provided with a compartment for housing a bushing or bearing made of frictionless material and locked in turn by an element mated with the cylindrical body and the bushing and fastened to the cylindrical body by means of a connecting element.

11. (Original) A valve as claimed in claim 9 wherein elements for guiding the movable assembly are integrated therein to prevent the contact between metallic surface during its motion.
